ASSIGNMENT-5

NAME	ROLL NO.
Apoorva Soni	20261651020
Kanishka Soni	20261651047
Diya Koshtha	20261651035

Q1. Show your :root palette. Why are named variables better than repeating hex codes across the file?

```
:root {
    --brand: #271259;
    --dark: #222;
}
```

Named variables are better because you can reuse the same color throughout the file and change it in one place, instead of repeatedly writing hex codes.

Q2. Give one use each of hex, rgb() and hsl() from your CSS, and say where you used a semi-transparent colour and why .

- **Hex:** #2563eb – used for a primary/brand colour.
- **RGB:** rgb(30, 41, 59) – used for a text colour.
- **HSL:** hsl(210, 40%, 98%) – used for a light background.

It can be used for a hover effect or a lightly highlighted section, where the background colour should remain partly transparent so the content/background underneath is still visible.

Q3. Why prefer rem over px for fonts and spacing? Show one calc() and one clamp() you used and what each does.

We prefer rem over px for fonts and spacing because rem scales relative to the root font size, making the layout more adaptable to the user's font-size settings.

Example: width: calc(100% - 2rem);

calc() performs a calculation, here making the width equal to the available width minus 2rem.

Example: font-size: clamp(1rem, 2vw, 1.5rem);

clamp() keeps the font size between 1rem and 1.5rem while allowing it to grow responsively with the viewport**.**

Q4. A box has width: 200px; padding: 20px; border: 5px. What is its actual rendered width with contentbox , and with border-box? Which did you use and why?

Given: width: 200px; padding: 20px; border: 5px;

With content-box (default): 200 + 20 + 20 + 5 + 5 = 250px

Actual rendered width = 250px

With border-box: The declared 200px already includes padding and border.

Actual rendered width = 200px

I would use: box-sizing: border-box;

because it makes sizing easier to predict and prevents padding and borders from unexpectedly increasing an element's overall width.

Q5. Name the four layers of the box model, from the inside out.

From inside to outside:

1. Content
2. Padding
3. Border
4. Margin

Q6. What does repeat(auto-fit, minmax(15rem, 1fr)) do, and why does it need no media query?

grid-template-columns: repeat(auto-fit, minmax(15rem, 1fr));

This creates as many columns as can fit while ensuring that each column is at least 15rem wide.

- auto-fit → automatically fits the available columns.
- minmax(15rem, 1fr) → each column is at least 15rem and can grow to share the available space.

It needs no media query because CSS Grid automatically changes the number of columns according to the available width.

Q7. Mobile-first: why write the phone styles as the base and add layout with min-width queries? And why is the viewport tag essential?

In mobile-first design, phone styles are written as the base styles: Base = mobile

Then larger layouts are added using:

@media (min-width: 768px) {

}

This is useful because the simple layout works on small screens first, and additional space is used progressively on larger screens.

The viewport tag is essential:

<meta name="viewport" content="width=device-width, initial-scale=1.0">

It tells mobile browsers to use the device's actual screen width instead of treating the page like a wider desktop page.

Q8. Paste your grid-template-areas map. Which regions span more than one column, and how did you make them?

```
.container {
   display: grid;
```

```
    grid-template-areas:
      "header header"
      "events events"
      "schedule registration"
      "footer footer";
}
```

The header, events, and footer regions span more than one column because their names are repeated across both columns in grid-template-areas. I made them span multiple columns by writing the same area name in both column positions.

Q9. Name one responsive technique for images and one for type that need no media query

For images:

```
img {
    max-width: 100%;
    height: auto;
}
```

This allows an image to shrink with its container.

For typography:

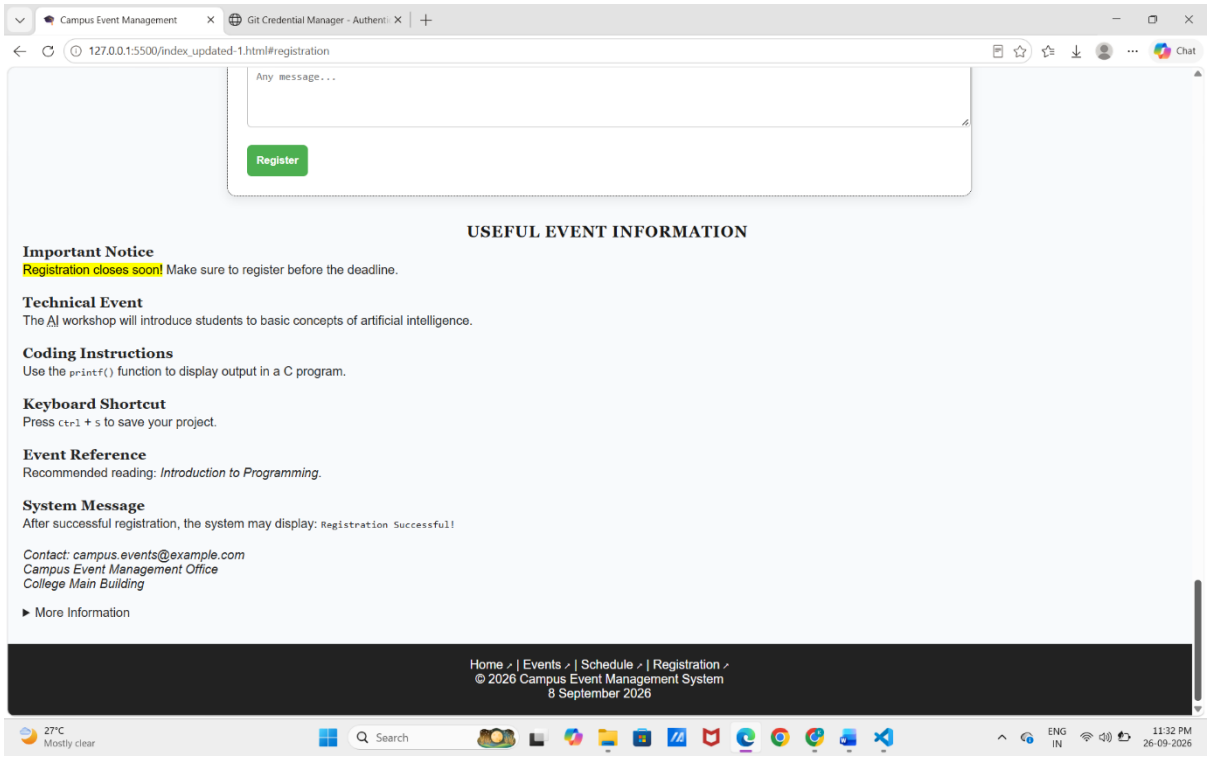

```
h1 {
    font-size: clamp(2rem, 5vw, 4rem);
}
```

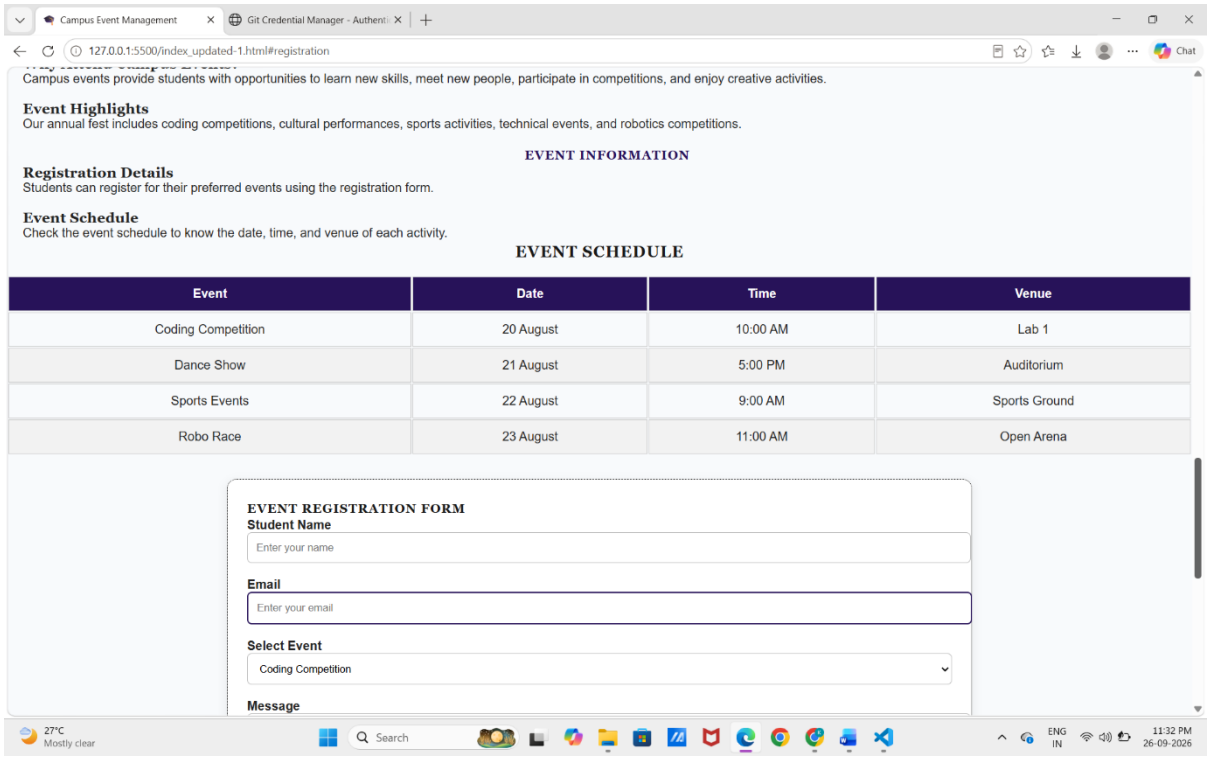

clamp() makes the text responsive without requiring a media query.

Q10. Prepare a GitHub repo for event-board and paste your final index.html and final style.css – the outcome of all the assignments. Give the repo link (and Pages link if live), and confirm it has a README and a readable commit history.
